Abstract

Reactions of dihetaryl and aryl/hetaryl thioketones with 2-diazopropane, diazoethane, and (trimethylsilyl)diazomethane were studied at variable temperature. The experiments showed that reactions with 2-diazopropane carried out at -75 °C occur mainly via the initially formed, relatively stable 1,3,4-thiadiazolines as products of the [3 + 2]-cycloaddition of the diazo dipole onto the C=S bond. The latter decompose only at higher temperature (ca. -40 °C) to generate thiocarbonyl *S*-isopropanide. In the absence of the starting thioketone, the corresponding thiiranes and/or ethene derivatives, formed from them via spontaneous desulfurization, are the main products. In contrast, reactions with diazoethane occurred predominantly via initially formed diradicals, which in cascade processes gave sterically crowded 4,4,5,5-tetrahetaryl-1,3-dithiolanes as major products. Finally, the reaction of dihetaryl thioketones with (trimethylsilyl)diazomethane occur smoothly at -75 °C leading to the corresponding 4,4,5,5-tetrahetaryl-1,3-dithiolanes as the exclusive [3 + 2]-cycloadducts formed via a cascade of postulated diradicals. The presence of S or Se atoms in the hetaryl rings is of importance for stabilizing diradical intermediates. Remarkably, in no single case, the 'head-to-head dimerization' of aryl/ hetaryl and dihetaryl substituted thiocarbonyl ylides was observed.

Introduction

Cycloaddition reactions belong to the most important classes of organic reactions, and [3 + 2]- cycloadditions, also known as 1,3-dipolar cycloadditions or Huisgen reactions, offer a universal tool for the preparation of five-membered heterocycles with a variable number of heteroatoms in the ring [1,2].

In addition to their practical importance, discussions on the mechanism contribute significantly to the development of fundamental concepts in organic chemistry [3-7]. The first general concept of concerted [3 + 2]-cycloadditions was formulated by Huisgen [4]. However, some time later, Huisgen and

co-workers reported stepwise [3 + 2]-cycloadditions via zwitterionic intermediates [8,9]. Large differences of energies of the frontier orbitals of dipole and dipolarophile, as well as sterically demanding groups at the terminus of the dipole, were pointed out as requirements for the initiation of the 'zwitterionic pathway'. In addition to the experimental findings, new reports dealing with computational studies aimed at the demonstration of new zwitterionic [3 + 2]-cycloadditions were published [10-12]. Finally, a third concept for the interpretation of the mechanism of [3 + 2]-cycloadditions, formulated by Firestone, is based on the assumption that they occur via diradical intermediates [13-15].

Reactions of aromatic thioketones with diazomethane are well established. For example, in the case of thiobenzophenone (1a), the reaction performed at -65 °C occurs without evolution of N₂ and the in situ formed 2,2-diphenyl-1,3,4-thiadiazoline **2a** can be subsequently used as a precursor of the reactive thiobenzo-

phenone S-methanide (a thiocarbonyl ylide) **3a** at ca. -45 °C, when the evolution of N₂ takes place [16-20]. An analogous course of the reaction with diazomethane was observed in the case of thiofluorenone (**1b**, Scheme 1).

When the decomposition of 2a or 2b was performed in the presence of a suitable dipolarophile, the corresponding [3 + 2]-cycloadducts were formed, whereas in the absence of a dipolarophile, the 'head-to-head dimerization' leading to 2,2,3,3tetraaryl-1,4-dithianes **4a**,**b** is the exclusive reaction.

Heteroatoms such as S and Se are known to stabilize radical centers [21]. In our ongoing studies on thioketones and their applications in the cycloaddition chemistry, we described in a recent publication the unexpected course of the reaction of diazomethane with aryl/selenophen-2-yl thioketones of type 1c, leading to unusual dimers 5 of intermediate thiocarbonyl ylides of type 3c [22] (Scheme 2). In a competitive reaction, the latter

react with the starting thioketone 1c to give 1,3-dithiolanes of type **6** which are, apparently, also formed via a diradical pathway, leading to the sterically crowded 4,4,5,5-tetrasubstituted isomers exclusively.

In other studies, performed with cycloaliphatic thioketones, e.g. with adamantane-2-thione or 2,2,4,4-tetramethyl-3-thioxocyclobutanone, the growing stability of the corresponding 1,3,4-thiadiazolines obtained in reactions with diazomethane, diazoethane, and 2-diazopropane was reported based on kinetic data [9,17-19]. The same tendency was observed in a series of reactions with aromatic thioketones: for example, the reaction of thiobenzophenone (**1a**) with diazoethane performed at -70 °C led to the formation of a relatively stable 2-methyl-1,3,4-thiadiazoline, which could be identified in the low temperature ¹H NMR spectrum [20]. To the best of our knowledge, there are no reports on the course of reactions of either diaryl, aryl/ hetaryl or dihetaryl thioketones with 2-diazopropane.

Prompted by these observations, we decided to examine reactions of aryl/hetaryl and dihetaryl thioketones 1 with some diazomethane derivatives, such as 2-diazopropane (7a), diazoethane (7b), and (trimethylsilyl)diazomethane (7c), and to compare their outcome with earlier reported reactions with diazomethane [22]. An important question was if in these reactions the corresponding 2-substituted 1,3,4-thiadiazolines of type 2 can be obtained at low temperature and subsequently used as precursors of new thiocarbonyl ylides. The latter may be potentially useful for the [3 + 2]-cycloaddition reactions with diverse dipolarophiles leading to five-membered S-heterocycles, such as di- and tetrahydrothiophenes, 1,3-oxathiolanes, 1,3dithiolanes, etc.

Results and Discussion

The first experiment performed with thiobenzophenone (1a) and 2-diazopropane (7a) at ca. -75 °C in THF led to a change of the blue color of the solution without evolution of N₂. The addition of the solution of 7a was continued until the color of the mixture changed to pale red. The mixture was warmed up, and around 0 °C the evolution of N₂ was observed. The ¹H NMR analysis of the crude product revealed the presence of only one singlet for two Me groups located at 1.62 ppm. After chromatographic work-up, the only product isolated as colorless crystals was identified as 2,2-dimethyl-3,3-diphenylthiirane (8a; Scheme 3, Table 1). The same result was obtained when the reaction was carried out at ca. -60 or -15 °C.

Similar experiments were performed with thiofluorenone (1b) and 7a. Whereas at -75 °C and -60 °C the corresponding thiirane 8b and ethene 9b, formed via spontaneous desulfurization of 8b, were obtained as the sole products, in the experiment carried out at -15 °C, the sterically crowded 1,3-dithiolane 10b was also detected as a minor product (14% yield, Table 1). In the latter case, thiirane 8b and ethene 9b were found in 24 and 37% yield, respectively. According to the literature, reaction of thiobenzophenone (1a) with diazoethane (7b) performed at -75 °C led to 5-methyl-2,2-diphenyl-1,3,4-thiadiazoline as the exclusive product [20]. After warming the reaction mixture to room temperature, the only products observed in the mixture were 2,2-diphenyl-3-methylthiirane (8i) and 1,1diphenylpropene (9i) as the product of its desulfurization. On the other hand, the experiment with 1a and 7b performed at room temperature led to the 1,3-dithiolane 10i as the major product (87%) accompanied by small amounts of thiirane 8i and ethene 9i [23].

(7a), diazoethane (7b), and (trimethylsilyl)diazomethane (7c) (Table 1).

A different result was observed in the reaction of 7a with di(thiophen-2-yl) thioketone (1d). In that case, the reaction at -75 °C afforded also the expected thiirane 8d as the major product, accompanied by small amounts of the corresponding alkene 9d. However, in that case 4,4,5,5-tetrasubstituted 1,3-

dithiolane **10d** was also observed (7%). The amount of the latter product increased to 36% when the reaction was performed at -60 °C and to 58% at -15 °C. The corresponding experiments with **1c** and **7b** led to increased amounts of 1,3-dithiolane **10k**, established as 43% at -75 °C, 81% at -60 °C, and 85% at

methane (7c).

-15 °C (Table 1). The same tendency, i.e., an increasing amount of 1,3-dithiolanes **10** in the case of the less-substituted diazoethane (**7b**) and at higher temperature, was observed for the reactions with thiofluorenone (**1b**), di(selenophen-2-yl)-, (phenyl)(thiophen-2-yl)-, (phenyl)(selenophen-2-yl)-, and other aryl hetaryl thioketones **1** (Table 1). As mentioned before, in

some cases tri- and tetrasubstituted thiiranes partially underwent spontaneous extrusion of sulfur to form the corresponding tri- or tetrasubstituted ethene derivatives **9**. In these cases, complete desulfurization was achieved by treatment of the reaction mixture with tris(diethylamino)phosphine, and the respective ethenes **9** were isolated as the final products. It is worth mentioning that in the case of the non-symmetrical aryl/hetaryl thioketones 1c, 1f-h and 2-diazopropane (7a), the formed 1,3-dithiolanes 10 were isolated as mixtures of cis- and trans-isomers. In the ¹H NMR spectra, they could be identified based on the presence of two and one signal, respectively, for the Me₂C(2) group. The mixtures of 1,3-dithiolanes 10 obtained from the reactions of diazoethane (7b) with thioketones 1c,f consisted of only two instead of the expected three diastereoisomers. In all cases they belong to the same group of regioisomers. The regioselective formation of products 10 was proved by ${}^{13}C$ NMR spectroscopy: the signals attributed to C(2) were found in narrow regions at 54.9-59.4 ppm for 10c, 10f-h and 43.1-45.6 ppm for 10m,n, respectively. In addition, the structure of the sterically crowded 4,4,5,5-tetrasubstituted aryl/ hetaryl 1,3-dithiolanes 10 could be confirmed by the presence of only two signals for the three C(sp³)-atoms of the heterocycle, whereas in the isomeric 2,2,4,4-tetraaryl/hetaryl 1,3dithiolanes, three signals for these atoms are expected (cf. [19]).

Trimethylsilyldiazomethane (7c) is widely applied as a practical and useful synthetic equivalent of the hazardous diazomethane [24,25]. In our earlier publications, its reactions with thiofluorenone (1b) and S-methyl (phosphonyl)dithioformate, leading to the expected 1,3,4-thiadiazoline derivatives, which are stable at -60 °C, were reported [26,27]. At higher temperature, in both reactions, dimers of the intermediate thiocarbonyl S-(trimethylsilyl)methanides were formed in the absence of a dipolarophile after evolution of N2. An analogous test experiment with 7c and thiobenzophenone (1a) was carried out in the course of the present study at -75 °C, and in this case slow decolorization of the reaction solution was observed. In contrast to the experiment with 1b, complete decolorization of the blue reaction solution was observed before the addition of the total, equimolar amount of 7c. After warming up and typical work-up procedure, the corresponding 1,3-dithiolane 100 and 1,4dithiane 4c in a ratio of 2:1 were found as products identified in the ¹H NMR spectrum of the crude reaction mixture. Thus, in this reaction dimerization of the intermediate thiocarbonyl ylide and its reaction with another molecule of 1a were competitive pathways. Finally, the reactions of 7c with symmetrically substituted dihetaryl thioketones 1d and 1e were performed at -75 °C, and in both cases, the sterically crowded 4,4,5,5-tetrahetaryl-1,3-dithiolanes 10r and 10s, respectively, were obtained as sole products.

The obtained results can be explained by the assumption that in the case of hetaryl thioketones **1** stepwise mechanisms via diradical intermediates govern the formation of the isolated 1,3dithiolanes **10** (Scheme 3). Based on earlier studies, the stability of 1,3,4-thiadiazolines **2**, which are considered as potential precursors of thiocarbonyl ylides **3**, should be increased by the introduction of Me or Me₃Si groups. Upon this assumption, all reactions performed at -75 °C should lead to the corresponding cycloadducts 2 with complete conversion of the starting thicketones 1. Only after warming up above -45/40 °C compounds 2 are expected to decompose yielding the reactive thiocarbonyl vlide 3. Under these conditions, the latter intermediates can undergo either 1,3-dipolar electrocyclization to give thiiranes 8 or dimerization leading to 1,4-dithianes 4 [20,26]. This reaction course resulting in the exclusive formation of thiiranes 8 was observed in the case of thiobenzophenone (1a) and thiofluorenone (1b) with 2-diazopropane (7a). However, the reaction of 1b with 7a carried out at -15 °C yielded also a small amount of 1,3-dithiolane 10b. This result can be interpreted by the partial decomposition of 2b in the presence of the non-converted thicketone 1b. The replacement of aromatic thicketones 1a,b by di(thiophen-2-yl) thioketone (1d) in the reaction with 7a resulted in the formation of comparable amounts of thiirane 8d and 1,3-dithiolane 10d, whereas at -75 °C 8d is again the major product. It is worth mentioning that the analogous experiment carried out at -60 °C, i.e., below the expected decomposition temperature of 1,3,4-thiadiazoline 2d, led to substantial increase of the amount of 10d. A similar tendency was observed in other studied cases with hetaryl thioketones and 7a. The replacement of the latter by diazoethane (7b), leading to the less stable 1,3,4thiadiazolines 2, resulted in a general increase of the corresponding 1,3-dithiolanes 10, which were formed in substantial amounts, even in experiments performed at -75 °C. However, the most striking results were observed in reactions performed with dihetaryl thioketones 1d and 1e with trimethylsilyldiazomethane (7c). In both experiments, the only products formed were the corresponding, sterically crowded 4,4,5,5,-tetrahetarylsubstituted 1,3-dithiolanes 10r and 10s. These results clearly demonstrate that 7c, similarly to diazomethane [22], reacts smoothly with dihetaryl thicketones 1 with no formation of the expected 1,3,4-thiadiazolines 2 and after release of N2 even at low temperature, the intermediate diradicals of type 3 attack the parent thioketones 1 yielding 1,3-dithiolanes 10 via stabilized 1,5-diradicals 12. In both cases no tendency for the formation of dimers of the intermediate 'thiocarbonyl ylide' was observed (Scheme 4).

Based on these results, the reaction mechanism can be proposed as formulated in Scheme 4. It seems likely that the first step comprising the reaction of a hetaryl thioketone 1 with 7a, 7b, and 7c is not a concerted process, but the diradical or zwitterionic intermediate of type 11 is formed and, depending on the number and type of stabilizing substituents and the reaction temperature, they undergo two competitive reactions: elimination of N₂ leading to thiocarbonyl ylide 3 or 1,5-ring closure to give 1,3,4-thiadiazoline 2. When the rapid elimination of N₂ occurs in the presence of the non-converted thioketone 1, the

stabilized 1,5-diradical **12** is formed as precursor of the sterically crowded 1,3-dithiolane **10**. The alternatively formed 1,3,4thiadiazolines **2a** and **2b** are expected to be stable at -75 °C and eliminate N₂ only at enhanced temperature generating thiocarbonyl ylide **3**. As in that case the starting diaryl (or dihetaryl) thioketone **1** is completely consumed, the 1,3-dithiolane **10** cannot be formed. The results obtained with **7c** demonstrate that its reaction with dihetaryl thioketones **1** occurs without formation of 1,3,4-thiadiazolines as intermediate [3 + 2]-cycloadducts. Elimination of N₂ from the initially formed diradical of type **11** leads immediately to the new diradical species **3**, which adds regioselectively to the C=S group of the non-converted thioketone **1**.

This interpretation is consistent with the course of the reactions of aryl/hetaryl thioketones **1** with diazomethane, in which the formation of sterically crowded 1,3-dithiolanes side-by-side with 12-membered dimers of the thiocarbonyl ylide was observed [22]. In addition, it corresponds to the diradical mechanism postulated for the formal [3 + 2]-cycloaddition of aryl/

hetaryl thioketones 1 with the in situ generated thiocarbonyl *S*-methanides [28]. The missing formation of dimers from thiocarbonyl ylides 3 derived from hetaryl thioketones can be explained by steric hindrance resulting from the presence of the Me or Me₃Si groups in the *S*-methanide moiety. However, electronic effects resulting from the diradical nature of the intermediate thiocarbonyl ylides, can also play certain role. The same effect was observed in the case of diaryldiazomethanes used in reactions with aryl/hetaryl thioketones [29,30].

Experimental

General information: Melting points were determined in capillaries using a MEL-TEMP II apparatus (Aldrich) and are uncorrected. IR spectra were recorded with a FTIR NEXUS spectrophotometer as KBr pellets or as film; absorptions (v) in cm^{-1} . ¹H and ¹³C NMR spectra were measured on a Bruker Avance III (¹H at 600 and ¹³C at 150 MHz) instrument in CDCl₃; chemical shifts (δ) are given in ppm, solvent signals as reference, coupling constants (J) in Hz. The multiplicity of the ${}^{13}C$ signals was deduced from DEPT, supported by ¹H, ¹³C HMQC spectra. ¹H NMR data are presented as follows: chemical shift, multiplicity (br = broad, s = singlet, d = doublet, t = triplet, q = quartet, m = multiplet), coupling constant, integration. The mass spectra were recorded on a Finnigan MAT-95 (ESI). Elemental analyses were performed in the Microanalytical Laboratory of the Chemistry Faculty of the University of Łódź. Applied reagents such as 2-diazopropane (7a) and diazoethane (7b) were prepared by known methods according to the literature protocols [31,32]. Thiobenzophenone (1a), fluorene-9thione (thiofluorenone, 1b), symmetrical dihetaryl thioketones 1d,e, and nonsymmetrical aryl/hetaryl thioketones 1c, 1f-h were obtained from the corresponding ketones using the known procedures [33]. Other reagents used in the present study were commercially available.

Reaction of thioketones 1a–h with 2-diazopropane (7a) and diazoethane (7b) – General procedure: Corresponding thioketones 1a–h (1 mmol) were dissolved in freshly distilled THF (2.5 mL) and the solution was cooled to the corresponding temperature (-15, -60, -75 °C; acetone/dry ice). Then, the mixture was treated with small portions of ethereal 2-diazopropane (7a) or diazoethane (7b) solution, until the intense color of the thioketone vanished. Then, the mixture was allowed to warm slowly to rt (ca. 2–4 h). After removal of the solvent under vacuum, the residue was subjected to ¹H NMR analysis in CDCl₃ solution with a weighed amount of 1,1,2,2-tetra-chloroethane as a standard. Crude products were purified by CC (CHCl₃/hexane 2:8).

In crude mixtures obtained from 2-diazopropane (7a) and thioketones 1c,e,g,h and from diazoethane (7b) and thioketones

1b–f, the presence of thiirane and the corresponding ethylene was evidenced based on the ¹H NMR spectra. In these cases, no isolation of the thiirane was performed; after addition of tris(dimethylamino)phosphine desulfurization leading to the ethane derivative was carried out.

Reaction of thioketones 1d–e with (trimethylsilyl)diazomethane (7c) – General procedure: The corresponding thioketones 1d–e (1 mmol) were dissolved in freshly distilled THF (2.5 mL) and the solution was cooled to -75 °C (acetone/ dry ice). Then, the mixture was treated with small portions of an ethereal solution of 7c (1 mmol). The mixture was kept in a cold bath, and the intense color of the thioketone vanished after 15 min. Subsequently, the mixture was allowed to slowly warm to rt (ca. 2–4 h). After removal of the solvent under vacuum, the residue was subjected to the ¹H NMR analysis in CDCl₃ solution with a weighed amount of 1,1,2,2-tetrachloroethane as an internal standard. Crude products were purified by CC (CHCl₃/hexane 2:8).

2,2-Dimethyl-3,3-diphenylthiirane (8a): Yield: 182 mg (76%). White crystals; mp 66–67 °C (chromatographic purification); IR (KBr) v: 2987 (w), 2921 (w), 1596 (w), 1490 (m), 1443 (m), 773 (m), 747 (m), 705 (s), 691 (m) cm⁻¹; ¹H NMR (600 MHz, CDCl₃) δ 7.60–7.58 (m, 4H, H_{arom}), 7.31–7.29 (m, 4H, H_{arom}), 7.23–7.21 (m, 2H, H_{arom}), 1.62 (s, 6H, CH₃) ppm; ¹³C NMR (150 MHz, CDCl₃) δ 142.4 (for 2 C_{arom}), 129.4, 127.9, 126.8 (for 10 CH_{arom}), 67.8, 52.9 (C-2, C-3), 27.9 (2 CH₃) ppm; ESIMS *m/z* (%): 241 (100, [M + H]⁺); anal. calcd for C₁₆H₁₆S (240.36): C, 79.95; H, 6.71; S, 13.34; found: C, 79.69; H, 6.50; S, 13.40.

1,1-Di(thiophen-2-yl)-2-methylpropene (**9d**): Yield: 4 mg (2%). Yellow oil; IR (film) v: 2927 (w), 2908 (w), 2850 (w), 1436 (m), 1369 (m), 1227 (m), 1016 (w), 827 (m), 693 (s) cm⁻¹; ¹H NMR (600 MHz, CDCl₃) δ 7.29 (d, J = 5.4 Hz, 2H, H_{arom}), 7.04–7.02 (m, 2H, H_{arom}), 6.91 (d, J = 3.6 Hz, 2H, H_{arom}), 2.03 (s, 6H, CH₃) ppm; ¹³C NMR (150 MHz, CDCl₃) δ 144.9, 137.1 (C_{arom}, C_{arom}-C=), 126.6, 126.4, 124.9 (for 6 CH_{arom}), 122.9 (C=*C*(CH₃)₂), 23.3 (2 CH₃) ppm; anal. calcd for C₁₂H₁₂S₂ (220.35): C, 65.41; H, 5.49; S, 29.10; found: C, 65.31; H, 5.76; S, 28.81.

2,2-Dimethyl-4,5-diphenyl-4,5-di(thiophen-2-yl)-1,3-dithiolane (10f): Isolated as a mixture of *cis-*, *trans-*isomers (crude product ratio 65:35). Yield: 142 mg (63%). White crystals; mp 153–154 °C (MeOH/CHCl₃); IR (KBr) v: 3062 (w), 2919 (w), 1595 (w), 1490 (m), 1443 (m), 1231 (m), 1156 (m), 854 (w), 697 (s) cm⁻¹; ¹H NMR (600 MHz, CDCl₃) δ 7.59–6.68 (m, 32H, H_{arom}), 1.86 (s, 3H, CH₃-*cis*), 1.70 (s, 6H, CH₃-*trans*), 1.39 (s, 3H, CH₃-*cis*) ppm; ¹³C NMR (150 MHz, CDCl₃) δ 151.2, 149.8, 144.0, 142.9 (for 8 C_{arom}), 131.3, 131.1, 130.5, 127.5, 127.1, 127.0, 126.6, 126.1, 125.4, 125.2, 125.0 (for 32 CH_{arom}), 78.8, 78.4 (C-4 + C-5, for *cis* and *trans*), 55.4, 55.3 (C-2, *cis* and *trans*) 33.1 (CH₃-*cis*), 32.9 (for 2 CH₃-*trans*), 32.5 (CH₃-*cis*) ppm; anal. calcd for $C_{25}H_{22}S_4$ (450.70): C, 66.62; H, 4.92; S, 28.46; found: C, 66.46; H, 4.91; S, 28.33.

1,1-Di(thiophen-2-yl)-propene (9k): Yield: 52 mg (25%) – After desulfurization of tiirane **8k**. Yellow oil; IR (film) v: 3104 (w), 3071 (w), 2930 (w), 2908 (w), 2850 (w), 1438 (m), 1362 (w), 1249 (m), 1223 (m), 1036 (w), 850 (s), 836 (s), 818 (s), 695 (s) cm⁻¹; ¹H NMR (600 MHz, CDCl₃) δ 7.23–7.22 (m, 1H, H_{arom}), 7.01–7.00 (m, 1H, H_{arom}), 6.96–6.94 (m, 1H, H_{arom}), 6.90–6.89 (m, 1H, H_{arom}), 6.80–6.79 (m, 1H, H_{arom}), 6.71–6.70 (m, 1H, H_{arom}), 6.18 (q, *J* = 7.2 Hz, 1H, =CH), 1.74 (d, *J* = 7.2 Hz, 3H, CH₃) ppm; ¹³C NMR (150 MHz, CDCl₃) δ 129.4, 139.8, 146.8 (2 C_{arom}, C_{arom}, *C*=), 127.6, 127.0, 126.6, 126.3, 125.5, 124.8, 123.4 (6 CH_{arom}, =CH), 15.6 (CH₃) ppm; anal. calcd for C₁₁H₁₀S₂ (206.33): C, 64.04; H, 4.89; S, 31.08; found: C, 63.83; H, 4.98; S, 31.14.

2-Trimethylsilyl-4,4,5,5-tetra(thiophen-2-yl)-1,3-dithiolane (**10r**): Yield: 220 mg (87%). Yellow crystals: mp 152–154 °C (hexane/CH₂Cl₂); IR (KBr) v: 2951 (w), 1618 (w), 1424 (m), 1250 (s), 1232 (m), 1122 (m), 1077 (m), 1050 (m), 842 (s), 752 (s), 699 (s), 632 (m) cm⁻¹; ¹H NMR (600 MHz, CDCl₃) δ 7.23–7.22 (m, 2H, H_{arom}), 7.20–7.19 (m, 2H, H_{arom}), 6.96–6.95 (m, 2H, H_{arom}), 6.89–6.87 (m, 2H, H_{arom}), 6.83–6.81 (m, 4H, H_{arom}), 3.89 (s, 1H, ((CH₃)₃Si)*H*C), 0.34 (s, 9H, (CH₃)₃Si) ppm; ¹³C NMR (150 MHz, CDCl₃) δ 148.1, 146.1 (for 4 C_{arom}), 130.2, 129.4, 127.0, 125.6, 125.5, 125.4 (for 12 CH_{arom}), 74.9 (C-4, C-5), 36.5 (C-2), –1.53 ((CH₃)₃Si) ppm; anal. cald for C₂₂H₂₂S₆Si (506.89): C, 52.13; H, 4.37; S, 37.96; found: C, 52.44; H, 4.55; S,37.71.
