General information: All the reagents and chemicals were purchased from commercial sources and used without any further purification. Common laboratory solvents (LR grade) were purchased from domestic suppliers. Analytical thin layer chromatography was performed using E. Merck silica gel 60 F aluminium plates and visualized under UV 254 nm. NMR spectra were measured with Bruker 500, and 600 MHz instruments. Chemical shifts are reported in δ units, parts per million (ppm) downfield from TMS. Coupling constants (J) are in Hertz (Hz) and are unadjusted; therefore, due to limits in resolution, in

some cases there are small differences (<1 Hz) in the measured J value of the same coupling constant determined from different signals. Splitting patterns are designed as follows: s, singlet; d, doublet; t, triplet; dd, doublet of doublets; dt, doublet of triplets; tt, triplet of triplets; m, multiplet; br, broad. IR spectra were recorded on a Perkin–Elmer FT-IR RXI spectrophotometer and values reported in cm^{-1} . ESI-MS spectra were obtained on a LCQ Advantage Ion trap mass spectrometer (Finnigan thermo fischer scientific). All the compounds were characterized by ^1H NMR, ^{13}C NMR, IR, and ESI-MS/HRMS spectroscopy.

Typical experimental procedure for the amidine synthesis: In a 25 ml round bottom flask, aldehyde (1 mmol), amine (2 mmol)/2-aminopyridine (1 mmol), isocyanide (1 mmol), and MeOH (5 ml) were taken. To this reaction mixture I_2 (1 mol%) was added and the reaction mixture was stirred until completion of the reaction (TLC). Next the reaction mixture was evaporated to dryness using a rotary evaporator and the residue was purified by silica-gel column chromatography using a mixture of ethyl acetate-hexane as eluent in increasing polarity.

Characterization data for the synthesized compounds 4a-4q & 7a
