Alternative synthetic routes to 1,1-dimethylindene (2) and congeners; experimental procedures for 2, 1,1-dimethylindane (9), 3-methyl-1-phenylbutan-2-ol, N-(1,1-dimethylindan-3-ylidene)hydrazine, and N,N’-bis(1,1-dimethylindan-3-ylidene)hydrazine
Alternative synthetic routes to 1,1-dimethylindene (2) and congeners

Path A:
\[ \text{PhCH}_2\text{MgCl} + \text{Me}_2\text{CH-CHO} \xrightarrow{\text{S1}} \text{S2} \]

\[ \text{PPS} \rightarrow \text{S2} \rightarrow \text{OH} \rightarrow \text{S3} \rightarrow \text{NBS} \rightarrow \text{Br} \]

Path B:
\[ \text{CO}_2\text{H} \xrightarrow{\text{PPS}} \text{S4} \xrightarrow{\text{PPS}} \text{S5} \xrightarrow{\text{LiAlH}_4} \text{S6} \xrightarrow{\rho\text{TsOH}} \text{S7} \xrightarrow{\text{NBS}} \text{S8} \]

Path C:
\[ \text{Br}_2 \xrightarrow{\text{+ Br}_2} \text{S7} \xrightarrow{\text{+ S5}} \text{S8} \]

Scheme S1: Pathways A and B to olefin 2 and pathway C to 3-bromo-1,1-dimethylindene (3);
NBS = N-bromosuccinimide, PPS = polyphosphoric acid, ρTsOH = p-toluenesulfonic acid.

The method of Bogert and Davidson [S1] (path A in Scheme S1) furnished the alcohol S2, whose cyclization to give 1,1-dimethylindane (9) was performed with polyphosphoric acid (PPS) in place of conc. H_2SO_4 (90\% [S1]) so as to avoid any sulfonation of the aromatic ring. Monobromination of 9 with N-bromosuccinimide (NBS, 1 equiv or less) and the radical starter azobis(isobutyronitrile) (AIBN) afforded the hitherto unknown 3-bromo-1,1-dimethylindane (S3), which decomposed slowly above 110 °C with elimination of gaseous HBr and darkening. Therefore, slow distillation under a pressure of not less than 49 Torr was required to secure olefin 2 as the most volatile hydrocarbon. However, overbromination by NBS could not entirely be avoided even with a substoichiometric amount of NBS, so that the thermal HBr elimination generated some 3-bromoalkene 3 (shown in the lower left corner of Scheme S1) which appeared in the higher-boiling fractions of the distilled product.

The alternative procedure of Bosch and Brown [S2] (path B in Scheme S1) for preparing the olefin 2 can also be recommended if the dehydration of 1,1-dimethylindan-3-ol (S6) is carried out by distillation over 4-toluenesulfonic acid in place of oxalic acid or instead of an ester pyrolysis.
As already communicated, the precursor acid was conveniently cyclized with PPS to afford 1,1-dimethylindan-3-one (S5). This ketone was a productive precursor of S6; but it afforded only poor yields of 1,1-dimethylindane (9) under the usual Clemmensen or Wolff–Kishner conditions. In the latter attempt, the major portion of S5 and hydrazine hydrate produced the azine S8. This evasive behavior may have thwarted a proper characterization of the liquid hydrazone which also forms S8 on distillation. Therefore, we reconverted the azine S8 to the crude hydrazone through heating with hydrazine hydrate (path C). The subsequent treatment of S7 with elemental bromine in pyridine and Et2O furnished 3-bromo-1,1-dimethylindene (3) in modest but variable yields.

Experimental procedures

1,1-Dimethylindene (2) from 9 via S3 (path A). 1,1-Dimethylindane (9, 42.5 g, 291 mmol), N-bromosuccinimide (NBS, 51.86 g, 291 mmol), dry CCl4 (600 mL), and azoabis(isobutyronitrile) (AIBN, 100 mg) were placed in a round-bottomed flask fitted with a reflux condenser. Slow heating initiated violent boiling with formation of colorless succinimide. After final weak refluxing for 30 min, all NBS (the solid bottom phase) had been consumed. Upon cooling to rt, succinimide floated on the surface and was collected on a filter, then washed with CCl4 (3×). The combined CCl4 filtrates were concentrated in vacuo, and the residual 3-bromo-1,1-dimethylindane (S3), containing traces of the olefin 2 and the bromoalkene 3, was characterized by its 1H NMR spectrum (CDCl3, 200 MHz): δ 1.22 and 1.42 (2 s, 2 × 3H, 2 × 1-CH3), ca. 2.39 and 2.51 (AB part of an ABX system, 2J = 14.2 Hz, 3J = 4.1 and 7.0 Hz, 2H, 2 × 2-H), 5.48 (dd, X part, apparent 3J = 6.1 and 4.1 Hz, 1H, 3-H), 7.10 (m, 2H), 7.20 (m, 1H), 7.32 (m, 1H) ppm.

Purification of S3 by distillation was not feasible because of thermal HBr elimination that gave the olefin 2. Therefore, 2 was generated from this crude material through slow distillation: Yield 35 g (83%); bp 105–106 °C/49 Torr (reference [S2]: 57 °C/4.8 Torr; reference [S3]: 190–192 °C); 1H NMR (CDCl3, 220 MHz) δ 1.27 (s, 6H, 2 × 1-CH3), 6.24 (d, 3J = 5.5 Hz, 1H, 2-H), 6.53 (d, 3J = 5.5 Hz, 1H, 3-H), 7.07 (m, 2H), 7.16 (m, 2H) ppm. The higher-boiling fractions contained a small amount of 3-bromo-1,1-dimethylindene (3).

1,1-Dimethylindane (9). The alcohol S2 (3.90 g, 23.7 mmol) and polyphosphoric acid [20.2 mL of a mixture of phosphoric acid (85%, 100 mL) and P2O5 (210 g)] was warmed to 75 °C and stirred for 30 min. The biphasic product mixture was treated with ice-water and Et2O, and the separated aqueous layer was shaken with Et2O (2×). The combined Et2O layers were shaken with water (1×), aqueous NaOH (2 M, 1×), then washed with ice-water until neutral, dried over
Na₂SO₄, concentrated and distilled, affording pure 1,1-dimethylindane (9, 2.62 g, 67%) with bp 110–155 °C (bath temp.)/50 Torr (reference [S1]: 191 °C). ¹H NMR (CDCl₃, 200 MHz) δ 1.25 (s, 6H, 2 × CH₃), 1.91 (t, 3J = 7.2 Hz, 2H, 2 × 2-H), 2.88 (t, 3J = 7.2 Hz, 2H, 2 × 3-H), 7.14 (quasi-s, 4H, C₆H₄) ppm; IR (film) ν 2958, 1479, 756 cm⁻¹. Anal. calcd for C₁₁H₁₄ (146.2): C, 90.35; H, 9.65. Found: C, 90.40; H, 9.76.

3-Methyl-1-phenylbutan-2-ol (S2). A dry three-necked, round-bottomed flask (1 L) was fitted with a large pressure-equalizing dropping funnel and a double-walled reflux condenser carrying a drying tube. The flask was charged with magnesium turnings (19.7 g, 807 mmol), a strong magnetic stirring bar, and anhydrous diethyl ether (25 mL). Without stirring, the Grignard reaction was started through the dropwise addition of ca. 20 mL of the solution of benzyl chloride (102.1 g, 807 mmol) in anhydrous Et₂O (400 mL) and weak warming of the bottom layer of magnesium metal. As soon as signs of local boiling became visible, the stirrer was started and the remaining benzyl chloride solution was added dropwise at a rate (within 4 hours) which kept the Et₂O slightly boiling without external warming. This precaution served to prevent the formation of 1,2-diphenylethane and was successful since almost all of the Mg turnings had been consumed after further heating to reflux for 30 min. Without heating, a solution of 2-methylpropanal (S1, 58.3 g, 808 mmol) in anhydrous Et₂O (100 mL) was added dropwise to the vigorously stirred mixture within 150 min. After short final heating to reflux (30 min), the slow addition of distilled water (50 mL within 90 min) to the cooled and stirred mixture produced a white precipitate. The product-containing supernatant was decanted and set aside, while the precipitate was dissolved with aqueous H₂SO₄ (2 M, 400 mL), then shaken together with the supernatant in a big separation funnel (2 L), whereafter the separated (lower) aqueous layer was discarded. The Et₂O phase was shaken with water (3×), then aqueous NaOH (2 M, 2×), then water until neutral, and dried over K₂CO₃. Evaporation and distillation furnished the product alcohol S2 (55.3 g, 42%) with bp 112–113 °C/14 Torr (reference [S1]: 118–122 °C/14 Torr). ¹H NMR (CCl₄, 60 MHz) δ 0.92 (d, 3J = 6.2 Hz, 6H, 2 × CH₃), 1.55 (m, 1H, 3-H), 1.68 (broad s, 1H, OH), 2.52 and 2.65 (AB part of an ABX system, 2H, CH₂-1), 3.37 (dt, 1H, 2-H), 7.10 (quasi-s, 5H, C₆H₅) ppm.

N-(1,1-Dimethylindan-3-ylidene)hydrazine (S7). A suspension of the azine S8 (7.28 g, 23.0 mmol) and dry hydrazine hydrate (1.20 mL, 1.23 g, 24.7 mmol) in propan-1-ol (20 mL) was refluxed for 30 hours, affording a homogeneous, yellow solution. Propan-1-ol was removed in a rotary evaporator, whereupon the pot residue was diluted with cold cyclohexane (20 mL). The precipitating remnant azine S8 was separated by filtration, and the filtrate was concentrated at rt
to yield the crude hydrazone **S7** as an almost colorless, viscous liquid (7.16 g, 90%). $^1$H NMR (CCl$_4$, 60 MHz) $\delta$ 1.30 (s, 6H, 2 $\times$ CH$_3$), 2.42 (s, 2H, CH$_2$), 5.30 (broad s, NH$_2$), 7.23 (m, 3H, 5-/6-/7-H), 7.63 (m, 1H, 4-H) ppm. This material furnished the known [S6] 3-iodo-1,1-dimethyl-indene on treatment with elemental iodine and NEt$_3$ or gave **3** with elemental bromine in pyridine.

**N,N’-Bis(1,1-dimethylindan-3-ylidene)hydrazine (S8)**. A mixture of ethanol (30 mL), 1,1-dimethylindan-3-one (S5, 13.86 g, 86.7 mmol), and hydrazine hydrate (27.7 g, 554 mmol) was heated at 100 °C for 8 hours. Ethanol and unconsumed hydrazine hydrate were distilled off under 12 Torr at bath temperatures up to 140 °C, whereupon the residue was crystallized from methanol (20 mL) to yield shiny yellow platelets of the azine **S8** (5.73 g, 42% after repeated concentration steps). Mp 164–165 °C (methanol or cyclohexane); $^1$H NMR (CDCl$_3$ or CCl$_4$, 60 MHz) $\delta$ 1.38 (s, 12H, 4 $\times$ CH$_3$), 2.97 (s, 4H, 2 $\times$ CH$_2$), 7.40 (m, 6H, 2 $\times$ 5-/6-/7-H), 7.93 (m, 2H, 2 $\times$ 4-H) ppm; IR (KBr) v 3090, 3068, 3022, 2965, 2920, 2865, 1638 (C=N), 1605, 1468, 1321, 762 cm$^{-1}$. Anal. calcd for C$_{22}$H$_{24}$N$_2$ (316.4): C, 83.50; H, 7.65; N, 8.85. Found: C, 83.70; H, 7.73; N, 8.70.
