## General

TLC was performed on aluminum sheets precoated with silica gel 60 F254 (Merck). Visualization was achieved by immersing the plates into a $10 \%$ solution of phosphomolybdic acid (PMA) in ethanol followed by heating the plate. Flash column chromatography was carried out on silica gel $60(0.040-0.060 \mathrm{~mm}$, Merck) with distilled solvents. All commercially available reagents and anhydrous solvents were used as received. $p$-Nitrophenyl $\alpha$-Dmannopyranoside ( $p$ NP-Man $p$ ) and Jack bean $\alpha$-mannosidase were purchased from Sigma; swainsonine and DIM from Carbosynth. All reactions containing sensitive reagents were carried out under a nitrogen atmosphere. ${ }^{1} \mathrm{H}$ NMR and ${ }^{13} \mathrm{C}$ NMR spectra were recorded at $25^{\circ} \mathrm{C}$ with a Bruker AVANCE III HD 400 spectrometer. Chemical shifts are given in $\mathrm{ppm}(\delta)$ relative to the residual signal of the appropriate deuterated solvent used $\left(\mathrm{CDCl}_{3}\right.$, $\mathrm{CD}_{3} \mathrm{OD}, \mathrm{D}_{2} \mathrm{O}$ ). Optical rotations were determined on a Jasco P-2000 polarimeter at $20{ }^{\circ} \mathrm{C}$. High-resolution mass spectra were recorded with an Orbitrap Elite (Thermo Scientific) mass spectrometer with ESI ionization in positive mode. The compounds for biological assays were lyophilized before the use.

## General procedure for deprotection (Method B)

In a manner similar to [2], $20 \% \mathrm{HCl}(1 \mathrm{~mL})$ was added to a stirred solution of protected acetonide $(0.15 \mathrm{mmol})$ in $\mathrm{MeOH}(2 \mathrm{~mL})$ while cooling to $0^{\circ} \mathrm{C}$ (ice-water bath). After 15 min of stirring, the ice-water bath was removed and the reaction mixture was stirred at rt for 72 h . Next, HCl was carefully neutralized with solid $\mathrm{Na}_{2} \mathrm{CO}_{3}(950 \mathrm{mg}$, 1.5 equiv to HCl ). The resulting suspension was filtered, the filtration cake was washed with $\mathrm{MeOH}(5 \mathrm{~mL})$ and the filtrate was concentrated. The residue was suspended in DCM ( 5 mL ), filtered and the solvent was evaporated under reduced pressure. The crude product was purified by column chromatography.

The combined organic extracts were washed with water $(3 \times 10 \mathrm{~mL})$, dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$, filtered and the solvent was evaporated under reduced pressure. The crude product was purified by column chromatography.

## Enzyme assay

Recombinant soluble forms of Drosophila melanogaster Golgi (GMIIb) and lysosomal (LManII) $\alpha$-mannosidases as well as Caenorhabditis elegans Golgi $\alpha$-mannosidase AMAN-2 were produced in Pichia pastoris and enriched by ammonium sulfate precipitation or nickel chelation chromatography as previously described [3,4]. The $\alpha$ mannosidase from Canavalia ensiformis (JBMan) was purchased from Sigma. The mannosidase activity of these enzyme preparations were measured using $p$-nitrophenyl $\alpha$-D-mannopyranoside ( $p$ NP-Man; Sigma; 100 mM stock in dimethylsulfoxide) as a substrate at 2 mM final concentration in 50 mM acetate buffer of the relevant previously defined optimal pH , GMIIb and AMAN-2 at pH 6.0 , LManII at pH 5.2 , and JBMan at pH 5.0 ) and $0.5 \mu \mathrm{~L}$ of the enzyme ( $0.05 \mu \mathrm{~g}$ of protein for JBMan), in a total volume of $50 \mu \mathrm{~L}$ for $1-2 \mathrm{~h}$ at $37^{\circ} \mathrm{C}$. GMIIb was assayed in the presence of $0.5 \mathrm{mM} \mathrm{CoCl}_{2}$.
The lyophilized derivatives used in the assay were dissolved in DMSO to the final concentration 50 mM and further diluted to a desired concentration in water. These derivatives were preincubated with the enzyme in the buffer for 5 min at rt and the reaction was started by addition of the substrate. The reactions were terminated with two volumes $(0.1 \mathrm{~mL})$ of 0.5 M sodium carbonate and the production of $p$-nitrophenol was measured at 405 nm using a multimode reader Mithras LB943 (Berthold Technologies). The average or representative result of three independent experiments made in duplicate is presented. The $\mathrm{IC}_{50}$ values were determined with $2 \mathrm{mM} p \mathrm{NP}-\mathrm{Man}$. The $K_{\mathrm{i}}$ values were determined from Dixon plots of assays performed with $p$ NP-Man $(0.5-4 \mathrm{mM})$.

## Molecular modeling

Docking with Glide. The X-ray structure of recombinant Drosophila melanogaster Golgi $\alpha$-mannosidase II (dGMII, PDB ID: 3BLB) [5,6] was used as 3D enzyme models of human GMII and LMan for docking of the synthesized compounds with the GLIDE program [7,8] of the Schrödinger package. Protonation states of amino acid residues of the enzymes was calculated for the pH 6.0 (dGMII) using the Propka v. 2 program [9,10]. For docking with dGMII all crystallographic molecules of water at the active site of dGMII were deleted except one (WAT1820, numbering according to PDB ID: 3BLB). This water has been shown to be conserved in crystal structures of dGMII either with intact substrates or inhibitors [11-13]. In docking calculations, the catalytic acid (Asp341 of dGMII) was modeled either in the neutral (as Ash ${ }^{0}$ ) or ionized (as $\mathrm{Asp}^{-}$) form to see differences in prediction of binding poses of the docked ligands. The receptor box for the docking conformational search was centered at the $\mathrm{Zn}^{2+}$ ion cofactor at the bottom of the active site with a size of $39 \times 39 \times 39 \AA$ using partial atomic charges for the receptor from the OPLS2005 force field except for the $\mathrm{Zn}^{2+}$ and side chains of His90, Asp92, Asp204, Arg228, Tyr269, Asp270, Asp340, Asp341 and His471. For these structural fragments the charges were calculated at the quantum mechanics level with the DFT (Density Functional Theory) method (M06-2X) [13] using a hybrid QM/MM model (M06-2X/LACVP**:OPLS2005) [15-17] with the QSite [18,19] program of the Schrödinger package. The grid maps were created with no Van der Waals radius and charge scaling for the atoms of the receptor. Flexible docking in standard (SP) precision was used. The partial atomic charges of the docked ligands were calculated at the DFT level (M06-2X/LACVP**) [14,15] using the Jaguar program [20] of the Schrödinger package. All ligands were docked with the amino group at the pyrrolidine ring either in protonated and neutral forms. The potential for nonpolar parts of the ligands was softened by scaling the van der Waals radii by a factor of 0.8 for atoms of the ligands with partial atomic charges less than specified cut-off of 0.15 . The 5000 poses were kept per ligand for the initial docking stage with scoring window of $100 \mathrm{kcal} \mathrm{mol}^{-1}$ for keeping initial poses; the best 400 poses were kept per ligand for energy minimization. The ligand poses with RMS deviations less than $0.5 \AA$ and maximum atomic displacement less than $1.3 \AA$ were discarded as duplicates. The post-docking minimization for 10 ligand poses with the best docking score was performed and optimized structures were saved for subsequent analyses using the MAESTRO viewer [21] of the Schrödinger package.

QM/MM geometry optimizations. Geometries of selected complexes (inhibitor:enzyme) from molecular docking were subsequently optimized at the QM/MM level (BP86/LACVP*:OPLS2005) [15,17,22] using the Qsite $[18,19]$ program of the Schrödinger package. The following decomposed scheme was used: the QM part (more than 280 atoms) of the inhibitor:dGMII system consisted of $\mathrm{Zn}^{2+}$ ion, inhibitor, water molecule WAT1820 (described in the previous section) and amino acid residues (Asp92, Asp204, Asp341, Asp340, Asp270, Asp409, Asp472, Arg228, Arg876, His90, His471, Tyr267, Tyr269, Tyr727, Ser268, Trp95, Trp415, Phe206). The rest of the enzyme was included into the MM part and described by the OPLS2005 force field [17]. The QM/MM methodology (an additive scheme) with hydrogen caps on boundary QM atoms and electrostatic treatment at the interface between the QM and MM regions using Gaussian charge distributions represented on a grid (keyword HCAPESCHG=3) was employed. The neutral form of the pyrrolidine ring of the inhibitors and the ionized form of the catalytic acid Asp341 of dGMII were considered. These ionized forms were used based on previous $\mathrm{p} K_{\mathrm{a}}$ calculations of imino-D-lyxitols bound at the active site of dGMII [32].

FMO-PIEDA calculations. Pair interaction energy decomposition analysis (PIEDA) was used along the twobody FMO method [23-25]. From the QM/MM-optimized inhibitor:enzyme complexes active-site clusters
consisted of more than 30 amino acid residues, $\mathrm{Zn}^{2+}$ ion and the bound inhibitor were built using the Facio program [26]. The hybrid orbital projection operator (HOP) technique was used in the generation of fragments for the covalently bounded amino acids. The FMO calculations were performed using the second-order Møller-Plesset theory $[27,28]$ (MP2) with the $6-31 \mathrm{G}(\mathrm{d})$ basis and polarizable continuum model (PCM) [29]. The Gamess package [30,31] [version 30 June 2021 (R1)] was used. The virtue of the FMO technique is to predict pair interactions between the two structural fragments of the molecular system embedded within the electrostatic potential of the surroundings (IFIE - inter fragment interaction energy). FMO-PIEDA enables the separation of the interaction energy into physically interpretable

$$
\begin{equation*}
E_{\text {int }}=E_{\text {els }}+E_{\text {exch }}+E_{\mathrm{ct}-\mathrm{mix}}+E_{\mathrm{disp}}, \tag{1}
\end{equation*}
$$

The electrostatic energy $E_{\text {els }}$ originates from Coulomb-like interactions between the fragments, the exchange energy $E_{\text {exch }}$ arises for fermion particles, the electrons, and accounts for the Pauli repulsion of electrons between the fragments. $E_{\mathrm{ct}+\mathrm{mix}}$ is somewhat peculiar; it includes the charge transfer that results from electron transfer from occupied molecular orbitals of one fragment to the vacant virtual orbitals on the second fragment. The mixing part is basically an approximate polarization. Dispersion energy $E_{\text {disp }}$ originates from interactions of instantaneous fluctuations of dipoles on the fragments due to electron correlation. This method was recently used to analyze interaction energy in different biomolecular systems [32-37].

To understand an inhibitory effect of a substituent at C-5 of the inhibitor ring of 10, 20, 28, 29, 30, 31 and DIM, the inhibitor was divided into two fragments, the pyrrolidine ring structure ( $\mathrm{I}_{\mathrm{ring}}$ ) and the methyl moiety ( $\mathrm{I}_{\text {linker }}$ ) (in 10), (1S)-1-hydrox yethyl (in 20), (1R)-1-hydroxyethyl (in 28 and 29), hydroxymethyl (in 30 and 31) and ( $1 R$ )-1,2-dihydroxyethyl moiety in (DIM). Then, the interaction energy between the inhibitor and enzyme ( $\Delta E_{\text {I-E }}$ ) consists of the interaction energy between the pyrrolidine ring of the inhibitor and enzyme ( $\Delta E_{\text {ring-E }}$ ) and the interaction energy between the linker of the inhibitor and enzyme ( $\Delta E_{\text {linker-E }}$ ):

$$
\begin{equation*}
\Delta E_{\mathrm{I}-\mathrm{E}}=\Delta E_{\text {ring-E }}+\Delta E_{\text {linker-E }} \tag{2}
\end{equation*}
